

## ROCKY MOUNTAIN CCA SELF-STUDY EXAMINATION

## DIRECTIONS

- Clearly mark an "X" in the brackets next to the best answer to each question. Complete evaluation form and registration form.
- Tear out this page and place in envelope along with a \$15 check (processing fee) payable to the American Society of Agronomy (or fill out credit card information). Payment in U.S. currency only.
- Mail self-study exam and fee to: ASA c/o CCA Self-Study Exam, 677 S. Segoe Road, Madison, WI 53711.

*A passing exam score (70%) is worth 1.5 Rocky Mountain CEU's in soil and water management.*

## QUESTIONS

- Water always flows from
 

<input type="checkbox"/> a. Wet soil to dry soil	<input type="checkbox"/> c. Higher potential energy to lower potential energy
<input type="checkbox"/> b. Dry soil to wet soil	<input type="checkbox"/> d. Lower potential energy to higher potential energy
- When water flows through large soil macropores, and bypasses large areas of soil, this phenomenon is referred to as:
 

<input type="checkbox"/> a. Dispersion	<input type="checkbox"/> c. Saturated flow
<input type="checkbox"/> b. Hydraulic conductivity	<input type="checkbox"/> d. Preferential flow
- Which of the following pesticides would persist in the soil the longest under normal field conditions?
 

<input type="checkbox"/> a. Dicamba	<input type="checkbox"/> c. Picloram
<input type="checkbox"/> b. Malathion	<input type="checkbox"/> d. 2,4-D
- Hydraulic conductivity generally decreases as
 

<input type="checkbox"/> a. Soil water 'potential energy' increases	<input type="checkbox"/> c. Infiltration rates increase
<input type="checkbox"/> b. Soil water content decreases	<input type="checkbox"/> d. Soil water 'potential energy' decreases
- A pesticide with a high  $K_{OC}$  value will
 

<input type="checkbox"/> a. Sorb weakly to soil colloids	<input type="checkbox"/> c. Persist for long periods of time in soil
<input type="checkbox"/> b. Sorb strongly to soil colloids	<input type="checkbox"/> d. Degrade quickly in soil
- Which of the following soil conditions is most prone to compaction?
 

<input type="checkbox"/> a. A soil at field capacity	<input type="checkbox"/> c. A soil at permanent wilting point
<input type="checkbox"/> b. A frozen soil	<input type="checkbox"/> d. A highly aggregated soil
- Which of the following soils would most likely have the greatest initial infiltration (assume preferential flow is not a factor and the soils are dry)?
 

<input type="checkbox"/> a. Sandy loam	<input type="checkbox"/> c. Silt
<input type="checkbox"/> b. Clay loam	<input type="checkbox"/> d. Loam
- In general, the rate of water infiltration into a dry soil is initially
 

<input type="checkbox"/> a. Lower than infiltration into a wet soil	<input type="checkbox"/> c. Much lower than it is at steady state
<input type="checkbox"/> b. Higher than infiltration into a wet soil	<input type="checkbox"/> d. Similar to that of infiltration into a wet soil
- When all applied irrigation water infiltrates the soil, the infiltration rate is
 

<input type="checkbox"/> a. Equal to the rate of water being applied	<input type="checkbox"/> c. Greater than the rate of water being applied
<input type="checkbox"/> b. Less than the rate of water being applied	<input type="checkbox"/> d. Inversely proportionate to the rate of water being applied
- An advantage of using  $K_{OC}$  over  $K_D$  to measure a pesticide's general ability to sorb to soil is
 

<input type="checkbox"/> a. $K_{OC}$ is highly dependent of soil type
<input type="checkbox"/> b. $K_{OC}$ does not take into account the influence of organic carbon on sorptivity
<input type="checkbox"/> c. $K_{OC}$ is independent of soil type
<input type="checkbox"/> d. $K_{OC}$ is easier to measure
