Issued in furtherance of Cooperative Extension work, Acts of May 8 and June 30, 1914, in cooperation with the USDA. Larry Tidemann, Director of Extension, Associate Dean, College of Agriculture & Biological Sciences, South Dakota State University, Brookings. Educational programs and materials offered without regard for race, color, creed, religion, national origin, ancestry, citizenship, age, gender, sexual orientation, disability, or Vietnam Era Veteran status.

EC909: PDFed January 2003.

Sunflower

2002 South Dakota Hybrid Performance Trials Oilseed and Confection

Kathleen Grady, oilseed breeder and Extension specialist

Lee Gilbertson, senior ag research technician

SDSU Plant Science Department

Sunflower production is greatly affected by choice of hybrid. When selecting a hybrid, carefully consider characteristics such as seed yield potential, oil content, oil composition, maturity, stalk strength, and disease resistance. Choose hybrids with characteristics that best suit your needs and production practices.

Yield

Evaluate as much performance information as possible when selecting a hybrid. Give more weight to information from trials close to home and look at relative performance over many locations and years. Performance averaged over many tests is called "yield stability."

Good yield stability means that a hybrid may or may not be the best yielder at all locations but that it ranks high in yielding potential at many locations. A hybrid that ranks in the upper 20% at all locations exhibits better yield stability than one that is the top yielder at two locations but ranks in the lower 40% at two other locations.

To determine if one hybrid is better than another for a given trait, use the least significant difference (LSD 5%) value at the bottom of each data column. The LSD 5% value is a statistical way to indicate if a trait like yield differs when comparing two hybrids. If two hybrids differ by more than the indicated LSD value for a given trait, they would most likely differ again when grown under similar conditions.

For example, if the Ipswich test (Table 3) could be repeated in 2003 exactly as it was in 2002, the yield ranking of a hybrid that yielded 2018 lbs/A and one that yielded 1677 lbs/A might change places since their yield difference (341 lbs/A) is less than the indicated yield LSD value of 346 lbs/A. Within the accuracy level of the equipment used, there was no statistical difference in yield between the two hybrids when grown under the conditions that existed at Ipswich in 2002.

In contrast, if grown again under similar conditions, a hybrid yielding 1606 lbs/A at Ipswich in 2002 would likely be lower yielding than one that yielded 2018

lbs/A, because the difference between them in 2002 ($2018 - 1606 = 412$ lbs/A) exceeded the LSD value (346 lbs/A).

In this publication, the LSD value was used to compute a minimum or maximum value for a hybrid to achieve to be in the 'top group' for the trait measured. For example, at Ipswich (Table 3) the highest yielding hybrid in 2002 was Legend LSF142N (2018 lbs/A). To determine if any other hybrids were in the top yielding group at Ipswich, the LSD 5% value of 346 lbs/A is subtracted from the highest yield to produce a top group minimum of 1672 lbs/A ($2018 - 346 = 1672$). Any hybrids yielding 1672 lbs/A or more were in the top yield group at Ipswich in 2002. The top group values are computed similarly for other traits.

Note that for factors such as lodging or moisture where a low value is desirable, the top group value is expressed as a maximum value. To qualify for the top group, hybrids must not exceed the maximum top group value listed at the bottom of the column.

The coefficient of variability (C.V.) listed at the bottom of each data column is a relative measure of the amount of variation recorded for a particular trait expressed as a percentage of the mean for that trait. Generally, trials with low C.V. rates are more reliable for making hybrid choices than trials with higher C.V. rates. Trials with C.V. rates not exceeding 15-20% may be considered reliable.

Look at as many trials as possible. It is unlikely that environmental conditions of any particular test will be repeated in any future year.

Oil Content and Composition

Among similar-yielding hybrids, select the one with the highest oil content. The oilseed market pays a premium for over 40% oil (at 10% moisture) and discounts for less than 40% oil.

Oil type may also be important. Hybrids are available with 'traditional,' high-oleic, and mid-oleic (NuSun) oil

composition. Markets may pay a premium based on the composition of the oil produced by a particular hybrid. Some companies offer guarantees for NuSun oleic levels. Consistency of oleic levels for particular hybrids will be an important trait to evaluate, as data become available.

Maturity

Full-season hybrids generally yield higher than early hybrids. Maturity is especially important if planting is delayed. Often, with delayed planting, only an early hybrid will mature and exhibit its full yield potential. Yield, oil content, and test weight are often reduced when a hybrid is damaged by frost before it is fully mature. An earlier hybrid will likely be drier at harvest than a later hybrid, thus reducing drying costs. To spread risk and workload, consider planting several hybrids with different maturity dates.

Moisture Content

Harvesting sunflower at moisture contents as high as 20-25% may reduce bird damage and seed shattering loss during harvest. Seed must be dried to 9.5% or less for storage.

Disease Resistance

The most economical and effective means of sunflower disease control is the planting of resistant or tolerant hybrids and a minimum of four years rotation between successive sunflower crops.

Most sunflower hybrids in the U.S. have resistance to Verticillium wilt, races 1 and 2 of downy mildew, and to two or more races of rust. Consult the seed company for information on the reaction of a particular hybrid to these and other diseases that may pose a risk in your growing area.

2002 Trials

Locations and Hybrids

Oilseed hybrid sunflower trials were planted at four locations in South Dakota (the Dakota Lakes Research Station near Pierre, Ipswich, Miller, and Pukwana). Entries in the oilseed sunflower trials included traditional oil hybrids, NuSun (mid-oleic) hybrids, and one high-oleic hybrid. Non-oilseed (confection) sunflower trials were conducted at Dakota Lakes, Miller, and Pukwana. Trial sites are indicated on the map in Figure 1. Lists of hybrids planted at each site appear in Tables 2 and 7.

Also included in this publication are the results of the National Sunflower Association (NSA) NuSun and confection hybrid sunflower trials conducted at Agar and Selby, S.D. (Tables 11-14). These trials were planted and harvested by Dakota Crop Services, Fargo, N.D. SDSU personnel took notes on the plots during the growing season.

Climatic Conditions

The 2002 growing season was very dry. The season began with approximately 40% of the state rating short to very short in topsoil and subsoil moisture. By mid-September, 50% of the state was short or very short in topsoil moisture and 65% was short to very short in subsoil moisture (South Dakota Ag Statistics Service).

A summary of 2002 climatic conditions near the sunflower test sites is presented in Table 1. All stations received below-normal growing season precipitation. Dakota Lakes received 6.34 inches less moisture than

normal for the months of May through September. Plots at Dakota Lakes were not harvested due to excessive drought, lodging, and bird damage.

Temperatures were generally below normal in May and August, but above normal in June, July, and September. Most of the state received a killing frost during the second week of October.

Experimental Methods

Plots at all locations consisted of two rows 23 feet long, spaced 30 inches apart. Plot layout was a randomized complete block design with four replications at each location. The experiments were randomized for a nearest neighbors statistical analysis, which removes effects of field trends (see Crop Science 34:62-66).

All plots were overseeded and thinned. Stands were spotty at Ipswich due to patches of Canadian thistles. Where excess plants were present, oilseed plots at Ipswich and Miller were thinned to a plant population of approximately 17,000 plants/A. Stands were fair to good at Pukwana and Miller. Oilseed plots at Pukwana were thinned to approximately 18,000 plants/A. Confection plots at all locations were thinned to 16,000 plants/A.

The Dakota Lakes trial was seeded no-till. All other trials were planted with conventional tillage practices. Spartan and Prowl herbicides were applied for weed control at Dakota Lakes. Sonalan or Treflan were applied at all other locations.

Flowering was recorded at Ipswich as the number of days from planting to 50% ray petals extended. Plant height and lodging notes were taken at all locations immediately before harvest. Lodging was lowest at Ipswich, ranging from 0% to 19%. There was heavy lodging at Pukwana and Miller, especially in the first replication of the oilseed trial at each location, which was therefore excluded from all data analyses. Plots at Dakota Lakes were excessively damaged by drought, lodging, and birds; they were not harvested.

Plots were harvested with a Gleaner Model K combine fitted with a two-row all row crop header. All oilseed trial seed yields were adjusted to 10% moisture. Oil content was determined by NMR analysis of oven-dry samples and converted to 10% moisture. Oil values for NuSun hybrids were adjusted according to the formula: $(\text{original NMR \%} \times 0.953) + 0.7148 = \text{true NuSun oil \%}$.

Seeds from the non-oilseed trials were dried before weighing. A one-pint subsample of seed from each plot was passed over 22/64, 20/64, and 18/64 round-hole screens to determine percent large seed. Nutmeat percent was determined by weighing 20 whole seeds, dehulling, and weighing the 20 dehulled kernels.

Results

Data from each location and combined over locations are contained in Tables 3-6 (oilseed) and 8-10 (confection). The highest average seed yield across oilseed hybrids was 1609 lbs/A at Ipswich, and the lowest was 1095 lbs/A at Pukwana. Non-oilseed seed yields averaged 1324 lbs/A at Miller and 1112 lbs/A at Pukwana. In the tables that follow, hybrids are listed according to 2002 seed yields.

Results from the NSA NuSun and confection trials are presented in Tables 11-14. Yields from the Selby NuSun trial are not reported because the C.V. % was too high for reliable hybrid comparisons. Average yield over all hybrids at Agar was 3042 lbs/A in the NuSun trial (Table 11) and 2916 lbs/A in the confection trial (Table 13). Confection hybrids at Selby averaged 1043 lbs/A seed yield (Table 14).

Presentation of data in this report on the hybrids tested does not imply approval or endorsement by SDSU to the exclusion of other varieties that may be suitable. South Dakota State University approves the reproduction of any table in this publication only if no portion is deleted.
